Vector search #2 – Text embeddings

Text

Sequence of tokens

- Query items
 - Keywords
 - question...
- Database items
 - Document
 - Paragraph
 - Sentence
 - Passage...
- Tokens \rightarrow units than can be enumerated 1..W
 - Convenient: words
 - n-grams overlapping or not
 - Tokenization

When I visited Antananarivo in Madagascar, a supp<mark>urative</mark> exudate was flowing from my nose.

https://platform.openai.com/tokenizer

Word statistics

- 10k 1M
 - Vocabulary of the language
 - Named entities
- Normalization (stemming)
 - Normalize upper/lower case
 - Remove plural
 - Remove conjugations
 - Remove declension
 - Split words for morphologically rich languages

Kaasschaafverkoper

Very unbalanced

- Common:
 - \circ A, the, it, etc.

• Less common:

60026	exudative	j
60027	shakti	n
60028	shearling	j
60029	sheerly	r
60030	short-selling	n
60031	phytic	j
60032	piedmontese	j

Bag of words

Bag of words

- The set of words in a document
- Discard order: "bag"
 - Keep counts
 - $\circ \quad \text{Word} \rightarrow \text{number in 1..W}$

• Sparse vector of size W (6 non-zeros / 10k)

Match words between query and database docs

I ride a bike in Paris.

Paris has more and more bike lanes.

Bike rides in Amsterdam

- Inverted index
 - \circ Map word \rightarrow list of documents that contain the word
 - o "Inverted list"
 - Word stemming (remove plural)
 - Stop words (common words)

а	1
Amsterdam	3
and	2
bike	1, 2, 3
has	2
in	1, 3
lane	2
more	2
Paris	1, 2
ride	1,3

TF-IDF weighting

- How important is a term (word) to a document?
- TF: term frequency
 - More important if the term appears more in the doc
- IDF: inverse document frequency
 - More important if the term is more rare in the corpus D
 - $\circ \quad \text{For common terms} \to \text{near 0}$
 - Justifies stop words

$$\operatorname{tfidf}(t,d,D) = \operatorname{tf}(t,d) \cdot \operatorname{idf}(t,D)$$

$$ext{tf}(t,d) = rac{f_{t,d}}{\sum_{t'\in d} f_{t',d}}$$
,

۰.

$$\mathrm{idf}(t,D) = \log rac{N}{|\{d \in D: t \in d\}|}$$

Search with TF-IDF weighting

- TF-IDF weights in inverted list entries
- Sum query term entries over documents to get scores

3 Ranked results

Equivalence with sparse matrix-vector product

- Inverted file = CSR
 - Compressed Sparse Row representation
- Efficient implementation (see scipy.sparse)

BM25 ranking

- Widely used variant of TF-IDF
 - Depends on scalar parameters

$$ext{score}(D,Q) = \sum_{i=1}^n ext{IDF}(q_i) \cdot rac{f(q_i,D) \cdot (k_1+1)}{f(q_i,D) + k_1 \cdot \left(1-b+b \cdot rac{|D|}{ ext{avgdl}}
ight)}$$

$${
m IDF}(q_i) = {
m ln}igg({N-n(q_i)+0.5\over n(q_i)+0.5} + 1 igg)$$

About word matching

• Good performance

- Fast
- Excellent for keyword queries "python io module"
- BOW = sum of individual word embeddings

- Limitation
 - Exact matching
 - "Tall" is as different from "large" as "small"

- Unable to take semantics into account
 - Purely statistical

Embedding discrete items

Creating embeddings for discrete items

- A set of items
 - We don't have/use a priori information (Fields, properties, etc.)
 - We need embeddings for them in some dimension d

- Relations between items
 - Sparse observations
 - Scores

- Find embeddings
 - such that similarities explain the relations
 - Nearby embeddings \rightarrow high scores
 - $\circ \quad \text{Far away embeddings} \rightarrow \text{low scores}$

A step aside: recommender systems

- N users
 - Customers

$$\{u_1, ..., u_N\} \in \mathbb{R}^d$$

- M items
 - \circ Products, movies, etc. $\{v_1,...,v_M\}\in \mathbb{R}^d$
- Score for user i, item j: $s_{i,j} \in \mathbb{R}$
 - Direct: stars, grades, ...
 - Indirect: previous purchases, clicks,...
- Regularity:
 - similar users tend to choose similar items
 - "Collaborative filtering"

Recommender systems – optimization

• Reproduce scores with dot product between user and item

$$s_{i,j} \approx \langle u_i, v_j \rangle$$

- Predict non-observed scores
- Formalization:
 - Objective = minimize the loss
 - Linear algebra works best with quadratic loss...

$$\text{Loss} = \sum_{(i,j)\in S} (s_{i,j} - \langle u_i, v_j \rangle)^2$$

Recommender systems – all scores known

• If the full score matrix was known

$$S = \{1, ..., N\} \times \{1, ..., M\}$$

• Matrix formulation

$$U = [u_1, ..., u_N], V = [v_1, ..., v_M], R = [s_{ij}] \in \mathbb{R}^{N \times M}$$

$$\mathrm{Loss} = \|UV^{\top} - R\|_{\mathrm{F}}^2$$

- Low-rank approximation of R
 - Matrix factorization
 - \circ SVD, see Edo's class

Recommender systems – iterative solution

- S is not full...
 - otherwise what's there to recommend?

$$\operatorname{Loss} = \sum_{(i,j)\in S} \left(s_{i,j} - \langle u_i, v_j \rangle \right)^2$$

- Random initialization of parameters
- Iterate
 - Pick a random sample x of training set S
 - Update the parameters in the direction of the gradient
 - Learning rate

$$\text{Loss} = \sum_{x \in S} f(x, \theta)$$
$$\theta = \{u_i, ..., u_N, v_1, ..., v_M\}$$

f

$$\theta_{t+1} = \theta_t - \lambda \frac{\partial f(x,\theta)}{\partial \theta}$$

Exercise:

• Compute the gradient

$$\frac{\partial f(x,\theta)}{\partial \theta}$$

• Complexity of a gradient step?

End side step

• Embeddings for a set of items can be built from relationships

- Usually not as simple
 - Need regularization term
 - Normalization
 - $\circ \rightarrow$ Integrates smoothly in iterative algorithm
 - Sampling strategies –
- Tradeoff on dimensionality d:
 - \circ If d is too small \rightarrow insufficient capacity, not accurate
 - \circ If d is too large \rightarrow overfitting unable to generalize

Machine learning with SGD

- Train a function y = f(x, theta)
 - Given a training dataset {x_i, y_i}
 - Iterative optimization of theta
- Interaction between 4 components
 - A function that is "sufficiently complex" for the task: the neural net
 - A loss function that reflects the task, sum over training examples
 - A way to present the dataset
 - An optimization algorithm: how to update the theta ?
- Subtle craftsmanship
 - little guidance from theory 😕
 - Many methods don't work unless parameters are set properly – trial and error – sweeps
 - details in the papers are important!

Word embeddings

Word2vec

- Trained on corpus of documents
 - No additional information (supervision)
 - Trained on docs with 1B words total

• Pull together words that are nearby in document text

- Skip-gram model
 - "Predict" a missing word from context
 - Probabilistic formulation (not really used)

Skip gram model

- Current word representation: u_w
- Neighboring word representations: v_w
 - Neighborhood size: c=3

For instance, any given movie can, to a rough degree of approximation, be described in terms of some basic attributes such as overall quality, whether <u>it's an action</u> **movie** <u>or a comedy</u>, what stars are in it, and so on. And every user's preferences can likewise be roughly described in terms of whether they tend to rate high or low, whether they prefer action movies or comedies, what stars they like, and so on.

- Pull together u_*movie* and v_*action*, v_*or*, v_*a*, v_*comedy*
- Then move on to the next word ("or")

Basic formulation

whether it's an action movie or a comedy, what stars w_{t-3} w_{t-2} w_{t-1} w_t w_{t+1} w_{t+2} w_{t+3}

- Compare embeddings with dot product
- Use "SGD friendly" optimization objective
 - With softmax
 - Also has probabilistic interpretation

Practical implementation

- Bottleneck is the softmax computation
 - Complexity O(d * W)
 - Can be approximated with hierarchical softmax
- Negative sampling
 - Replace softmax with log of sigmoid
 - Encourage large dot product but not too much
 - And a sample of k "noise" words N(t, j)

$$Score(t,j) = \log(\sigma \langle u_{w_t}, v_{w_{t+j}} \rangle) - \sum_{w \in N(t,j)} \log(\sigma \langle u_{w_t}, v_w \rangle)$$

- Subtle choice of sampling
 - Based on word frequencies

Both NCE and NEG have the noise distribution $P_n(w)$ as a free parameter. We investigated a number of choices for $P_n(w)$ and found that the unigram distribution U(w) raised to the 3/4rd power (i.e., $U(w)^{3/4}/Z)$ outperformed significantly the unigram and the uniform distributions, for both NCE and NEG on every task we tried including language modeling (not reported here).

Evaluation of word embeddings: nearest word

Nearest words

• Limited capability...

Model	Redmond	Havel	ninjutsu	graffiti	capitulate

Adjective to adverb	apparent	apparently	rapid	rapidly	1	
Opposite	possibly	impossibly	ethical	unethical		
Comparative	great	greater	tough	tougher		
Superlative	easy	easiest	lucky	luckiest		
Present Participle	think	thinking	read	reading	Syntactic	
Nationality adjective	Switzerland	Swiss	Cambodia	Cambodian	(10675)	
Past tense	walking	walked	swimming	swam		
Plural nouns	mouse	mice	dollar	dollars		
Plural verbs	work	works	speak	speaks	↓	

Word arithmetic

Somewhat surprisingly, these questions can be answered by performing simple algebraic operations with the vector representation of words. To find a word that is similar to *small* in the same sense as *biggest* is similar to *big*, we can simply compute vector X = vector("biggest") - vector("big") + vector("small"). Then, we search in the vector space for the word closest to X measured by cosine distance, and use it as the answer to the question

• The country-to-capital vector:

• Dependence on dim vectors:

Dimensionality / Training words	24M	49M	98M	196M	391M	783M
50	13.4	15.7	18.6	19.1	22.5	23.2
100	19.4	23.1	27.8	28.7	33.4	32.2
300	23.2	29.2	35.3	38.6	43.7	45.9
600	24.0	30.1	36.5	40.8	46.6	50.4

[Bojanowski & al. Enriching Word Vectors with Subword information, ACL'17]

Word embeddings with sub-words (fastText)

• Collect all n-gram sub-words for a word

3	<ti< td=""><td>til</td><td>ili</td><td>lin</td><td>ing</td><td>ng></td></ti<>	til	ili	lin	ing	ng>
4	<til< td=""><td>tili</td><td>ilin</td><td>ling</td><td>ing></td><td></td></til<>	tili	ilin	ling	ing>	
5	<tili< td=""><td>tilin</td><td>iling</td><td>ling></td><td></td><td></td></tili<>	tilin	iling	ling>		
6	<tilin< td=""><td>tiling</td><td>iling></td><td></td><td></td><td></td></tilin<>	tiling	iling>			

tiling

- Sum up n-gram embeddings + word embedding
 - \circ Hashed n-gram \rightarrow limited to 2M embeddings
 - Collisions unlikely...
 - Replace sub-word embedding in skip-gram model
- Same optimization as word2vec

Results on fastText

- Significant improvement on syntactic analogy
- Needs less training data
- Works better on morphologically rich languages

Table 7: Nearest neighbors of rare words using our representations and skipgram. These hand picked examples are for illustration.

Word translation

[Word translation without parallel data, Conneau et al, ICLR'18]

- Analogy task suggests there is a way to translate
 - Given translation of anchor words

• Maybe a rigid structure in word embeddings?

- Could we align them ?
 - $\circ \rightarrow$ effortless translation
 - W unitary matrix

 $y_{\rm it} \approx W x_{\rm en}$

Estimating W

• If there are a few word (<< vocabulary) correspondences

$$\begin{array}{rcl} X & = & [x_{\mathrm{en}}^1 & x_{\mathrm{en}}^2 & \cdots & x_{\mathrm{en}}^n] \\ Y & = & [y_{\mathrm{it}}^1 & y_{\mathrm{it}}^2 & \cdots & y_{\mathrm{it}}^n] \end{array}$$

- Then W can be estimated with
 - Closed form solution based on SVD

$$W^{\star} = \underset{W \in M_d(\mathbb{R})}{\operatorname{argmin}} \|WX - Y\|_{\mathrm{F}}$$

• Translation

$$t = \operatorname{argmax}_t \cos(Wx_s, y_t)$$

What if we don't have initial words?

- Use adversarial training
- Discriminator function D(x, theta)
 - Higher for source language (x)
 - Lower for target language (y)
 - Parameters theta
- Batches of (Wx, Wx, y, Wx, y, Wx, Wx)
- Step 1: optimize discriminator

$$Loss(\theta) = -\sum_{i} D(Wx_{i}, \theta) + \sum_{j} D(y_{j}, \theta)$$

• Step 2: optimize W to fool the discriminator

$$Loss(W) = \sum_{i} D(Wx_{i}, \theta) - \sum_{j} D(y_{j}, \theta)$$

Refinement with reliable word matches

- Select a subset of word pairs and re-estimate W
- How to select reliable pairs?
 - General method to select a subset of pairs
- k-NN search + additional criteria
- Reverse nearest neighbors
 - Wx must be a nearest neighbor of y
 - y must be a nearest neighbor of Wx
- CSLS criterion
 - Contrast with similarity to other neighbors

$$\operatorname{CSLS}(Wx_s, y_t) = 2\cos(Wx_s, y_t) - r_{\mathrm{T}}(Wx_s) - r_{\mathrm{S}}(y_t)$$

$$r_{\mathrm{T}}(Wx_s) = \frac{1}{K} \sum_{y_t \in \mathcal{N}_{\mathrm{T}}(Wx_s)} \cos(Wx_s, y_t)$$

Table 1: Word translation retrieval P@1 for our released vocabularies in various language pairs. We

Conclusion on word embeddings

- Rich semantic information
- Very simple to train
 - Outperforms multi-layer models
 - Needs lots of training data
- Emerging arithmetic properties
- Basis for the following
 - Input to more complex language models

Document embeddings

Multi-word embeddings

- Sequence of words
 - Whole documents
 - Sentence
 - phrase
 - Paragraph / passage
- Combinatorial size
 - Possible for 2-word units

Czech + currency	Vietnam + capital	German + airlines	Russian + river	French + actress

Check crown	Ho Chi Minh City	carrier Lufthansa	Volga River	Vanessa Paradis
Polish zolty	Viet Nam	flag carrier Lufthansa	upriver	Charlotte Gainsbourg
CTK	Vietnamese	Lufthansa	Russia	Cecile De

Table 5: Vector compositionality using element-wise addition. Four closest tokens to the sum of two vectors are shown, using the best Skip-gram model.

- \circ Cannot build a table of all document \rightarrow embedding
- What to do with embeddings?
 - Nearest neighbor search (Translation)
 - Question answering (context)

NP noun phrase PP preposition VP vector phrase

Word pooling

[Offline bilingual word vectors, orthogonal transformations and the inverted softmax, Smith et al, ICLR'17]

• Sum of word vectors

- Continuous bag of words (CBOW, not to be confused with the word2vec model)
- Possibly with IVF weighting (increase weight of less frequent words)
- Extension of the classical BOW (that is sparse)

• Works for sentence translation retrieval

- 2000 query sentences
- 200k targets that contain a translation of the sources
- Sentence embedding with words

Vector sum pooling exercise

• Given

- Set of n vectors uniform on sphere dimension d
- Fixed unit query vector q
- Compute
 - If all vectors are independent of q
 - If q is one of the vectors
- \rightarrow a general property of pooling

$$X = \sum_{i=1}^{n} X_i$$
$$E[\langle X, q \rangle] = ?$$
$$Var[\langle X, q \rangle] = ?$$

[A group testing framework for similarity search in high-dimensional spaces, Shi et al, ACM MM'14]

Sentence encoders

A language model

Ο

[Improving Language Understanding by Generative Pre-Training, Radford et al, OpenAI tech report '18]

Probabilistic formulation Sequence of tokens

$$\mathcal{U} = \{u_1, \ldots, u_n\}$$

Predict next token's likelihood given a context Ο window of size k

$$L_1(\mathcal{U}) = \sum_i \log P(u_i | u_{i-k}, \dots, u_{i-1}; \Theta)$$

Given by a neural net with parameters Theta

- At inference: does this belong to the language?
- Metric: perplexity
 - Lower = better Ο

$$PPL = \exp\left(-\frac{1}{n}L_1(\mathcal{U})\right)$$

- Unsupervised
 - Can be trained on any corpus of texts Ο
 - Larger is better... Ο

[Attention is all you need, Vaswani et al, NIPS'17]

Language models based on transformers

- Initially applied to sequence-to-sequence modeling
 - translation
 - Encoder + decoder, with supervision
- Input = sequence of token embeddings
 - Arbitrary length
 - $\circ \quad \text{Token} \to \text{look-up table}$
 - positional encoding

- Sequence of Blocks
 - Attention
 - Feed forward
 - Applied as residuals

The attention function

- Pass input through 3 linear layers \rightarrow Q, K, V
- Attention mechanism
 - Interaction between all vectors of the sequence
 - Row-wise softmax
 - Weighted sum of V matrix rows

Attention
$$(Q, K, V) = \operatorname{softmax}(\frac{QK^{T}}{\sqrt{d_{k}}})V$$

 $\sim -T$

Multi-Head Attention

- Multi-head
 - Vector decomposed into sub-vectors
 - Processed independently
 - Concatenated back in the end

[Survey on Self-Supervised Multimodal Representation Learning and Foundation Models, Thapa, arxiv'22]

What the attention pays attention to

• Hard to visualize

- Multiple layers
- Multiple heads...

• LARGE language models

- $\circ \quad \text{Add more layers } 12 \to 80$
- Increase embedding dimensionality 768 \rightarrow 1024
- Increase number of heads $12 \rightarrow 16$
- ... and increase context size!

Figure 3: An example of the self-attention mechanism following long-distance dependencies in the encoder self-attention. Many of the attention heads attend to a distant dependency of the verb 'making', completing the phrase 'making...more difficult' [Vaswani et al., 2017].

[H2O: Heavy-Hitter Oracle for Efficient Generative Inference of Large Language Models, Zhang et al, Arxiv'23]

Scaling up the context size

- More context:
 - More information for output
 - Up to 49k tokens
- Quadratic cost of Q * K
- Exploit attention sparsity
 - More sparse for upper layers
 - Find non-0 entries is max inner product search

- External memory...
 - Later in this class

BERT

[BERT: Pre-training of deep bidirectional transformers for language understanding, Devlin et al, ArXiV'19]

- Simpler use case than sequence to sequence
 - Just interested in embedding for one sequence

- Unsupervised pre-training
 - Large corpus
 - Language model-like task
- Supervised fine-tuning
 - Small corpus
 - Possibly small additional layer
 - 11 tasks in the original paper

BERT: pre-training

- Arbitrary tasks
- Begin sequence with [CLS]
- Masked LM
 - Special token [MASK]
 - Replace some words with [MASK]
 - Predict token from output representation (linear + softmax)
- Next sentence prediction
 - Separate sentences with [SEP]
 - Are the 2 sentences following each other?
 - From the [CLS] embedding

BERT fine-tuning (from the original paper)

Tested on 11 different tasks

- 1 or 2 sentences on input (with [SEP])
- Per-token prediction or per-sentence (with [CLS])
- + linear layer + softmax

- Example task: SQuAD
 - Find answer to question in a sentence / paragraph
 - Classifier for first token
 - Classifier for last token

BERT examples

Pre-training

Input = [CLS] the man went to [MASK] store [SEP]

he bought a gallon [MASK] milk [SEP]

Label = IsNext

Label = NotNext

Fine-tuning for SQuAD

In meteorology, precipitation is any product of the condensation of atmospheric water vapor that falls under **gravity**. The main forms of precipitation include drizzle, rain, sleet, snow, **graupel** and hail... Precipitation forms as smaller droplets coalesce via collision with other rain drops or ice crystals **within a cloud**. Short, intense periods of rain in scattered locations are called "showers".

What causes precipitation to fall? gravity

What is another main form of precipitation besides drizzle, rain, snow, sleet and hail? graupel

Where do water droplets collide with ice crystals to form precipitation? within a cloud

Emerging properties of LLMs

[Sparks of Artificial General Intelligence: Early experiments with GPT-4, Bubeck et al, ArXiV'23]

- Seem to be able to do some form of reasoning
 - \circ Syntactic relationships (just a word) \rightarrow more complex relationships
 - Especially in combination with language generation.

- Semantics
 - Input is semantically high level (human generated, encoded compactly)
 - Reasoning by analogy

Prompt: Here we have a book, 9 eggs, a laptop, a bottle and a nail. Please tell me how to stack them onto each other in a stable manner.

GPT-4:

One possible way to stack the objects onto each other in a stable manner is:

- Place the book flat on a level surface, such as a table or a floor. The book will serve as the base of the stack and provide a large and sturdy support.

- Arrange the 9 eggs in a 3 by 3 square on top of the book, leaving some space between them. The eggs will

form a second layer and distribute the weight evenly. Make sure the eggs are not cracked or broken, and handle them gently to avoid dropping them.

- Place the laptop on top of the eggs, with the screen facing down and the keyboard facing up. The laptop will fit snugly within the boundaries of the book and the eggs, and its flat and rigid surface will provide a stable platform for the next layer. Make sure the laptop is closed and turned off, and do not press any keys or buttons.

- Place the bottle on top of the laptop, with the cap facing up and the bottom facing down. The bottle will add some height and balance to the stack, and its cylindrical shape will reduce the contact area with the laptop. Make sure the bottle is empty and closed, and do not shake or tilt it.

- Place the nail on top of the bottle cap, with the pointy end facing up and the flat end facing down. The nail will be the final and smallest object in the stack, and its sharp tip will prevent it from rolling or sliding off the bottle. Make sure the nail is clean and straight, and do not touch or move it.

Sentence embeddings for retrieval

Contrastive learning

- f_\theta is a BERT
 - Average pooling of output token representations
- InfoNCE loss

$$s(q,d) = \langle f_{\theta}(q), f_{\theta}(d) \rangle.$$

$$\mathcal{L}(q,k_+) = -rac{\exp(s(q,k_+)/ au)}{\exp(s(q,k_+)/ au) + \sum_{i=1}^{K}\exp(s(q,k_i)/ au)},$$

- Computed per training batch
- Form of contrastive learning
 - Expressed as a classification objective
 - Degrees of freedom: positives ? negatives?

[Dense passage retrieval for Open-Domain Question answering, Karphukhin etal, ArXiv'20]

DPR – supervised

- Positive pairs:
 - (Question, answer) pair

- Negative pairs:
 - pairs from the same batch with high BM25 overlap

[Unsupervised dense information retrieval with contrastive learning, Izacard et al, ICML'22]

Contriever – unsupervised

- Positive pairs: independent cropping
 - Sometimes overlaps

It is a truth universally acknowledged, <u>that a single man in possession of a good fortune</u> must be in want of a wife. However little known the feelings or <u>views of such a man may be on his</u> <u>first entering a neighbourhood</u>, this truth is so well fixed in the minds of the surrounding families, that he is considered as the rightful property of some one or other of their daughters.

Negative pairs: momentum contrast

- previous batches
- Embeddings computed with slowly updating network

$$\theta_k \leftarrow m\theta_k + (1-m)\theta_q$$

[Beir: A heterogenous benchmark for zero-shot evaluation of information retrieval models, Thakur et al, ArXiV'21]

Contriever results

BEIR family of benchmarks (doc retrieval)

FEVER [60] The Fact Extraction and VERification dataset is collected to facilitate the automatic fact checking. We utilize the original paper splits as queries \mathbf{Q} and retrieve evidences from the pre-processed Wikipedia Abstracts (June 2017 dump) as our corpus \mathbf{T} .

Climate-FEVER [14] is a dataset for verification of real-world climate claims. We include the original dataset claims as queries **Q** and retrieve evidences from the same FEVER Wiki corpus **T**. We manually included few Wikipedia articles (25) missing from our corpus, but present within our relevance judgements.

SciFact [68] verifies scientific claims using evidence from the research literature containing scientific paper abstracts. We use the original publicly available dev split from the task containing 300 queries as our test queries \mathbf{Q} , and include all documents from the original dataset as our corpus \mathbf{T} .

- Also multilingual
 - Common embeddings
- DRAGON
 - Extensive study of data augmentations

Figure 2: Illustration of progressive label augmentation. For each iteration of training, additional relevance labels from a teacher are augmented in the training data. By contrast, uniform supervision directly exposes models to all the supervisions (as in iteration 3) in the beginning.

[How to Train Your DRAGON: Diverse Augmentation Towards Generalizable Dense Retrieval, Lin et al. ArXiV'23]

Table 2: **BEIR Benchmark.** We report nDCG@10 on the test sets from the BEIR benchmark for bi-encoder methods without re-ranker. We also report the average and number of datasets where a method is the best ("Best on") over the entire BEIR benchmark (excluding three datasets because of their licence). Bold is the best overall. MS MARCO is excluded from the average. "CE" refers to cross-encoder.

Generating answers

[Leveraging Passage Retrieval with Generative Models for Open Domain Question Answering Izacard & Grave, ArXiV'20]

The task

- Q&A
- Make a real answer

- Insert special tokens
- Supervised training of the seq2seq model
 - Pretrained T5 model (220-770M params)
 - Train on 64 GPUs

Figure 1: A simple approach to open domain question answering. First, it retrieves support text passages from an external source of knowledge such as Wikipedia. Then, a generative encoder-decoder model produces the answer, conditioned on the question and the retrieved passages. This approach scales well with the number of retrieved passages, as the performance keeps improving when retrieving up to one hundred passages. [Replug: Retrieval-augmented black-box language models, Shi et al, ArXiV'23]

RePlug

• Use perplexity of language model

Conclusion

- Embeddings in the text domain
- Word-level / sentence-level
- Tools
 - Metric learning
 - NCE
 - Pre-training / fine-tuning
 - Transformer models
- Natural way for information retrieval in a corpus of text docs

End
